

Providing A Network Communication Status Description Based  
On User Characteristics

5

Technical Field

This invention relates to providing a network  
communication status description based on user  
10 characteristics.

Background

Networks such as the Internet enable users all over  
the world to share information. For example, a Web-browser  
15 (e.g., Microsoft® Internet Explorer®) can retrieve web-pages  
from computers in almost any country. Such networks  
typically require network nodes (e.g., computers) to share a  
protocol that defines how the network nodes communicate.  
For example, computers on the Internet commonly communicate  
20 using HTTP (HyperText Transfer Protocol). HTTP defines  
messages that a client (e.g., a browser) can send to request  
information from a server. HTTP also defines messages that  
the server uses to send back the requested information. The  
HTTP messages typically travel through a number of  
25 intervening agents (e.g., proxies, routers, and firewalls) en  
route to their destinations.

As many "web-surfers" have experienced, obtaining  
information over a network is not always trouble-free. For  
example, information a user seeks may have been moved to a  
30 different computer. Additionally, the computer storing the  
information may be temporarily unable to provide the  
requested information, for example, when the computer  
receives too many requests at the same time.

A server can supply an error message for display by a  
35 browser or other client. For example, many Web users may  
have encountered a "404 - File Not Found" error message

during a browsing session. Unfortunately, error messages can be very technical and, therefore, have little meaning for novice computer users. Additionally, while network nodes in different countries share a communications protocol, computer users still speak a wide variety of languages. Thus, an error message in English is of little value to someone who only speaks French. A server administrator can configure a server to provide error messages in different languages.

### Summary

In general, in one aspect, a method of providing a network communication status description based on user characteristics includes receiving a status indication from a first networked computer in response to a user's request for information and determining one or more characteristics of the user who issued the request. The method provides a status description corresponding to the received status and the determined user characteristics.

Embodiments may include one or more of the following features. The method may further include transmitting the status description to a second networked computer.

The status indication may indicate the success or failure of the user's request. The status indication may be a status code such as an HTTP (HyperText Transfer Protocol) status code.

User characteristics may include technical proficiency. The technical proficiency may be inferred, for example, by basing the proficiency on a user's previous request or requests for information.

User characteristics may include one or more preferred languages. The preferred languages may be inferred, for example, by determining a user's address or access number used.

The status description may include text and/or speech data. The status description may include graphics, video, animation, sound, and instructions. The status description may be selected from a database of status descriptions.

5 In general, in another aspect, a method of providing a network communication status description based on user characteristics includes receiving an HTTP (HyperText Transfer Protocol) status code from a first networked computer in response to a user's HTTP request for a URL  
10 (Universal Resource Locator) provided by the first networked computer. The method also includes determining one or more characteristics of the user who issued the request, selecting a status description from a database of status descriptions based on the received HTTP status code and the determined  
15 user characteristics, and transmitting the status description to a second networked computer.

In general, in another aspect, a proxy for providing a network communication status description based on user characteristics includes means for receiving a status code  
20 from a first networked computer in response to a user's request for information, means for determining one or more characteristics of the user who issued the request, means for selecting a status description from a database of status descriptions based on the received status code and the  
25 determined user characteristics, and means for transmitting the status description to a second networked computer.

Advantages may include one or more of the following. By transmitting a status description in a user's preferred language(s), a user can quickly understand problems that  
30 occurred when the user requested information and can try to

remedy these remedy problems. By centralizing status descriptions in an intervening agent instead of duplicating the descriptions at different servers offering information, the servers need not waste processing time providing tailored  
5 status descriptions and need not provide storage for a large number of status descriptions. By providing status descriptions based on a user's technical proficiency, the techniques can provide a user with information likely to be of value to the user.

10 The details of one or more embodiments of the invention are set forth in the accompanying drawings and description below. Other features, objects, and advantages of the invention will be apparent from the description and drawings, and from the claims.

#### 15 **Drawing Descriptions**

FIG. 1 is a screenshot of a display that includes a status description in a user's preferred language.

20 FIG. 2 is a flowchart of a process for providing a status description in a user's preferred language.

FIG. 3 is a screenshot of a graphical user interface for specifying a user's preferred language(s).

FIG. 4 is a table of HTTP status categories.

FIG. 5 is a table of HTTP status codes.

25 FIG. 6 is a diagram illustrating storage of status information.

FIG. 7 is a diagram of a proxy that provides status information in a user's preferred language.

30 FIG. 8 is a diagram of a client that provides status information in a user's preferred language.

Like reference numbers and designations in the various drawings indicate like elements.

#### Detailed Description

5 Referring to FIG. 1, user requests for information (e.g., web-pages) from a network node can fail for a variety of reasons. For example, a user requesting an HTML (HyperText Markup Language) page stored on a remote computer on the World Wide Web may have mistyped a URL (Universal  
10 Resource Locator) identifying the page.

As shown in FIG. 1, a user's request for information has failed. A browser display 100 includes a status description 102 (e.g., text, graphics, video, animation, links, and sounds) explaining the cause of failure of the  
15 user's information request. The display 100 also includes an appended status description 104 based on the user's characteristics. As shown, the appended status description 104 is in a user's preferred language (e.g., English, German, French, Spanish, or Chinese). By providing status  
20 descriptions in a language more readily understood by a user, the user can quickly comprehend and try to remedy problems in retrieving requested information. For example, a user can identify typographical errors in an entered URL and transmit an information request with a corrected URL.

25 The tailored status description 104 can be provided based on different user characteristics such as the preferred language(s) of the user and/or the user's technical proficiency. For example, the status description 104 may simply state "HTTP Protocol Error: 404" to a very  
30 sophisticated user, but state "The file you entered doesn't

exist. Look for typos and try re-entering the location" to less experienced users. Descriptions provided to less experienced users may also include HyperText links or technical support telephone numbers for providing further assistance. By displaying a status description based on the user's technical proficiency, even users with little experience can quickly receive assistance.

Referring to FIG. 2, a process 106 for providing status descriptions based on a user's characteristics can include examining a server's response to an information request to determine the status (e.g., the success or cause of failure) of the request. The process 106 also determines characteristics of the user making the request. For example, the process 106 can determine the preferred language(s) and technical proficiency of the user. Based on the determined status and user characteristics, the process 106 can provide a status description that corresponds the user characteristics. The status description may be in a variety of formats such as HTML, XML (Extensible Markup Language), JPEG (Joint Picture Experts Group), MPEG (Moving Pictures Experts Group), etc. The provided status description can replace or be provided in addition to (e.g., appended or prepended) any status descriptions provided by the server that processed the information request.

The process 106 can determine the preferred language of a user in a variety of ways. For example, HTTP provides a "response-language" field in HTTP information requests. The response-language field can include an ordered list of ANSI-coded indications of the user's native language. For example, an ANSI-coded list of "1, 0, 2" corresponds to a

preference list of "French", "English", and "Danish". The user can define the contents of the response-language field by interacting with a browser user-interface. For example, a user can tailor Microsoft® Internet Explorer® by navigating through "Edit", "Internet Options", "General", "Languages" and entering different preferred languages. These entries are transmitted in each HTTP request. Referring to FIG. 3, America Online® provides users with the ability to declare a preferred language and stores the user's response in a database.

Alternatively, a user's preferred language can be inferred by identifying the access number dialed by a user to connect to a network or by accessing a user's billing or accounting information. Pending application "Data Localization", filed Dec. 22, 1998 (PCT/US/27217) describes methods of inferring characteristics of a user and is incorporated herein.

A user's technical proficiency can also be determined in a variety of ways. For example, a user can self report their abilities. Alternatively, technical proficiency can be inferred, for example, by tracking a user's success rate in obtaining information over a network (e.g., how many errors does a user accumulate when trying to access web-pages).

Referring to FIGS. 4 and 5, HTTP and other network communication protocols define status codes that describe the success or failure of network communications. These codes describe errors, application-specific messages, whether a request has been redirected, etc. These codes are transmitted in response to problems encountered in retrieving and transmitting requested information. For example, an HTTP

response message includes a "status-code" field that includes a numeric representation of the status. By examining the status-code of a response message, the process of FIG. 2 can determine which status description to provide. For example, if an HTTP response message is received having a "status-code" field equal to "401", the process can provide a status description that explains that the request was not "authenticated." Less experienced users may not know what "authenticated" means and the process can provide a less technical description.

Referring to FIG. 6, a status description database 122 includes status information for each status code 121 in a variety of different languages 123. The database 122 also stores multiple descriptions for the same language and status code that differ in the level of technical information provided 125. The database 122 enables a system to quickly retrieve a status description tailored to a user. As shown, database 122 records are keyed by status code 121, ANSI language value 123, and technical proficiency 125 (e.g., "novice", "experienced", and "expert"). A wide variety of other data storage techniques could similarly provide quick and easy access to a description.

In addition to or in lieu of a database, an intervening agent or client can use language translation software that translates text from one language to another. For example, SysTrans® can automatically translate text from English to Spanish. Using a database of pre-written information, however, can speed processing and avoid garbled sentences sometimes produced by translation software. Additionally, the use of translation software would not be

helpful in the cases where a server only responded with a status code and did not provide a status description.

Referring to FIG. 7, including instructions that provide a status description based on user characteristics 102 in a proxy 124 or other intervening agent enables the agent to provide tailored status descriptions for information requests that travel through the agent 124. This alleviates the need for each server offering information to store a large number of different status descriptions (e.g., [number of statuses] x [number of languages supported] x [number of different levels of technical explanation] x [average size of description]). Additionally, centralization of the processing instructions can eliminate the need for installing status descriptions in each client.

As shown in FIG. 7, when a client 122 issues an information request, the proxy 124 (e.g., an Internet Service Provider such as America Online®) forwards the request to a network server providing the requested information 126. When the proxy 124 receives the response from the network server, the proxy 124 can determine the status of the information request. If the response indicates successful operation, the proxy 124 can forward the received response to the client unaltered. Otherwise, the proxy 124 can determine one or more languages understood by a user, the user's technical proficiency, and other user characteristics to select a pre-written status description from a database 122 and transmit the selected description to the client.

Referring to FIG. 8, the instructions for providing a status description based on user characteristics 102 also can reside in a client 122 instead of in an intervening agent.

When the client 122 receives an information request response, the client 122 can determine the status of the information request. The client 122 then can provide a status description tailored to the user (e.g., in language(s) preferred by the user). The selected description then can be displayed by a browser or other application providing network services.

The methods and techniques described here may be implemented in digital electronic circuitry, or in computer hardware, firmware, software, or in combinations of them. Apparatus embodying these techniques may include appropriate input and output devices, a computer processor, and a computer program product tangibly embodied in a machine-readable storage device for execution by a programmable processor. A process embodying these techniques may be performed by a programmable processor executing a program of instructions to perform desired functions by operating on input data and generating appropriate output. The techniques may advantageously be implemented in one or more computer programs that are executable on a programmable system including at least one programmable processor coupled to receive data and instructions from, and to transmit data and instructions to, a data storage system, at least one input device, and at least one output device. Each computer program may be implemented in a high-level procedural or object-oriented programming language, or in assembly or machine language if desired; and in any case, the language may be a compiled or interpreted language. Suitable processors include, by way of example, both general and special purpose microprocessors. Generally, a processor will
